The carbon-catalyst interface can be optimized by maximizing the number of structural pores (NSPs) present within carbon support materials. Few techniques exist for the synthesis of NSPs in carbon nanotube (CNT) networks. Here we report a simple and effective approach for the formation of NSPs in CNT networks by oxidation-induced nanopore nucleation (OIN) of individual CNTs in metal-containing ionic liquid mixtures. The formation of NSPs in such CNT-ionic liquid-metal catalysts facilitated higher dispersion and co-ordination of the active species on the CNT backbone, and this led to significantly higher activity for the hydrogenation of nitrobenzene with the new catalyst. The new methodology also enabled the formation of NSPs in porous carbon supports with controlled pore size and high-surface areas. In the construction of a building or similar structure, whether large or small, that require the use of concrete or the like, the poured concrete or like mixture must remain in the specified form or shape until such time as curing has taken place. For example, when pouring the concrete or mortar mixture, the mixture is first applied to the surfaces of the form or mold, and then an appropriate finish surface is put over the top of the concrete, or the masonry wall or similar structure is put in place. The concrete or mortar mixture is usually allowed to set for a specified period of time, and then the formed concrete is released from the form. Conventional forms utilized for casting concrete and/or similar mixtures are normally temporary and thus are discarded once the casting operation is complete. Such conventional concrete or mortar forms are normally quite heavy and awkward to handle. Additionally, once concrete is cast, it is
